

Boiler

Protect your investment by performing regular scheduled maintenance on your boiler. Most manufacturers recommend that the boiler be cleaned periodically due to impurities introduced through the water supply.

Rust, both on the exterior and interior walls can cause your boiler to leak. Regular maintenance will help prevent rust build up.

All water supplies contain some mineral deposits and impurities; the degree varies with geographic location. We recommend a cleaning schedule that will keep your equipment in proper, safe working order where water supplies are relatively pure.

A stepped-up, more frequent cleaning schedule may be required when excessive impurities exist. The cleaning schedule should be performed two or more times per year, or as governed by the local water conditions. Protect the inner boiler walls and components against rust, scale and lime deposits.
